

CNS Vasculitis: A Review

M. Castillo, MD, FACR

University of North Carolina at Chapel Hill

Case 1. 45 y/o man w/progressive encephalopathy & strokes

Granulomatous angiitis

Vasculitis: Definition & Classification

- Inflammation & necrosis of blood vessel wall (artery & vein)
- Secondary:
 - More common
 - In context of well-defined disorders
- Primary:
 - Very rare, idiopathic
- Disorders that mimic vasculitis (vasculopathies):
 - Atherosclerosis, RCVS
 - Both may show vessel wall enhancement

Vasculitis (autoimmune): Classification

Large vessels	Medium vessels	Small vessels
<ul style="list-style-type: none">-Takayasu's-Giant cell (temporal arteritis)-Polymyalgia rheumatica	<ul style="list-style-type: none">-Polyarteritis nodosa-Kawasaki's	<ul style="list-style-type: none">-Non-ANCA*: Henoch Schonlein purpura (IgA vasculitis)-ANCA-associated: Wegener (granulomatosis w/polyangiitis), microscopic polyangiitis & Churg Strauss (eosinophilic)

- Most important in neuroradiology: Takayasu's, giant cell & Wegener
- Variable size vessels: Behcet & Cogan syndrome

ANCA = anti-neutrophil cytoplasmic antibody

Case 2. Child w/fever & left hemiplegia

Varicella Zoster Vasculitis

Varicella Zoster Vasculitis

- Due to reactivation of virus
 - Migration through nerve fibers innervating arteries
 - Arterial involvement in 70% of pts
- Involvement related to immune status:
 - Competent: MCAs
 - Deficient: distal arteries

Infection-related Vasculitis

- Other causes:
 - TB
 - Angiophillic fungi (aspergillus, mucormycosis)
 - Staph aureus
 - Syphilis

Tuberculosis

RadioGraphics 2014; 34: 873

Mucormycosis

Syphilis

Case 3. Young female w/decreased UE pulses

Takayasu's arteritis

Takayasu's Arteritis

- Incidence: 1: 3,000,000 (x100 in Asia)
- Predominantly women, 15-30 years of age
- Affects aorta & major arteries (including renal ones)
- Clinical:
 - Pre-pulseless phase: systemic symptoms, MRI: arterial wall enhancement, arterial dilatation
 - Occlusive phase, MRI: wall enhancement + narrowing

Takayasu's Arteritis

ARTERY	ABNORMALITIES %	CLINICAL MANIFESTATIONS
Subclavian	93%	UE claudication, Raynaud phenomenon
Common carotid	58%	Visual changes, stroke
Abdominal aorta	47%	Pain
Renal	38%	Hypertension, renal failure
Aortic arch	35%	Aortic insufficiency
Vertebral	35%	Visual changes, stroke
Pulmonary	20%	Chest pain, dyspnea
Celiac axis	18%	Abdominal pain

Pre-pulseless & occlusive phase

Giant Cell Arteritis

Case 4. Young female w/malaise, fever & strokes

Polyarteritis nodosa

Polyarteritis Nodosa, Medium-size Vessels

- Incidence: 2-9/1,000,000
- Rare in children
- Diagnosis: histological evidence of necrotizing vasculitis + skin lesions *or* myalgia *or* hypertension *or* neuropathy *or* renal involvement
- Imaging: vasculitis, microaneurysms are classic but not identified on imaging

Case 5. Clinical history withheld

Granulomatosis with polyangiitis A.K.A. Wegener

Granulomatosis w/polyangiitis, Mostly Small Vessels, cANCA +

- Incidence: 30/1,000,000, both genders equal, 30-50 yr of age
- 10-45% affect head & neck, 5% affect brain
- Brain: infarcts, demyelinating-like lesions, large pituitary, pachymeningitis
- Chapel Hill criteria (3): positive histology, renal/pulmonary/laryngotracheal *and/or* +cANCA

Case 6. Severe post partum headaches.

Reversible vasoconstriction syndrome

Post Partum Angiopathy (RVCS)

- Not “vasculitis”
- Rare, 1-2 weeks post partum (5 days)
- Symptoms: severe headaches, encephalopathy, seizures
- Predisposing factor: ergot in 30%
- MRI: normal in 70%, hemorrhage vasogenic edema (PRES-like) & bleeds in 30%
- DSA: abnormal in all

RVCS

Initial Vessel Wall MRI

Day 20 F/U

Vessel Wall MR Imaging

High res (MCA wall is 0.2-0.3 mm), 3D acquisition, low signal from CSF & flowing blood (T1 or proton density)

Better at 3T, isotropic voxel (0.4-0.7 mm)

Longitudinal Findings

Clinical & angiographic features correlate

With treatment, vascular wall enhancement diminishes on VWMRI

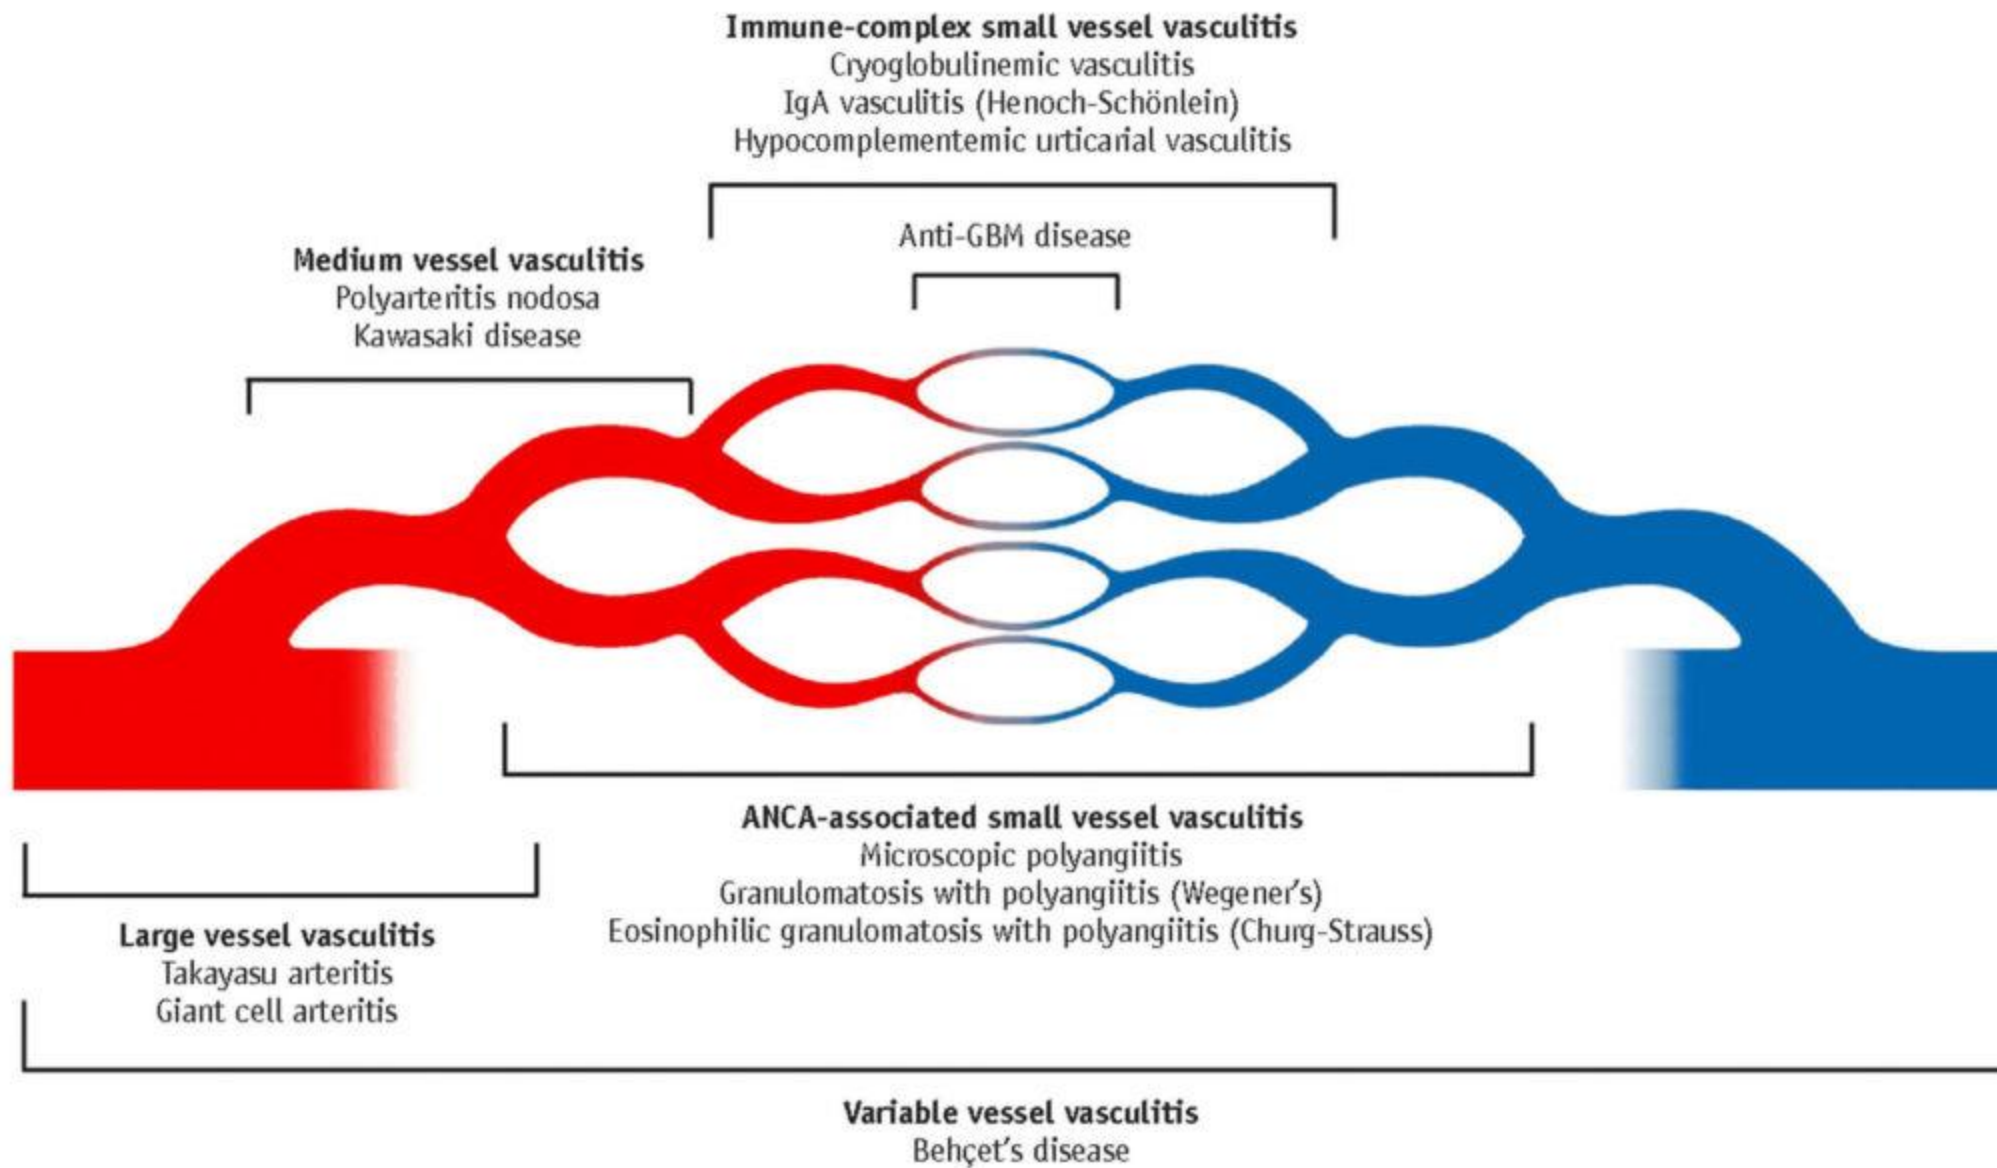

Smaller size vessels: DSA may be negative. PACNS

Again, diagnosis is difficult...

Granulomatous angiitis

SLE-related vasculitis

Conclusions

- DX of vasculitis is very difficult
- Clinical suspicion & inflammatory markers, predisposing factors
- MRI (DWI, T2, FLAIR, perfusion) is a good to start
 - High resolution vessel wall imaging is best
- MRA is not optimal, need DSA
- Most patients will need biopsy for DX (100% diagnostic)
- Thank you: M Mossa Basha, R Nunez Hoffman, S Petcharunpaisan
